LES (Large Eddy Simulation) has been used to fully reproduce the characteristics of the flow field in eccentric annular channels, rectangular channels and rod bundles, to verify and characterize the presence of large-scale coherent structures and to examine their behavior at different Reynolds numbers. The numerical approach is based upon boundary fitted coordinates and a fractional step algorithm; a dynamic Sub Grid Scale (SGS) model suited for this numerical environment has been implemented and tested. The agreement with previous experimental and DNS results has been found good overall for the streamwise velocity, shear stress and the rms of the velocity components. The instantaneous flow field presented large scale coherent structures in the streamwise direction at low Reynolds numbers, while these are absent or less dominant at higher Reynolds. POD (Proper Orthogonal Decomposition) of the flow field on both experimental and computational data has provided a basis on which the code validation is made.

Keywords: LES, POD, Eccentric channel, Advanced Nuclear Systems, Tight Lattice

1. Introduction

In this work extensive calculations have been carried out for the eccentric annulus channel flows as a simplified geometry in connection to the turbulent flows in tight lattice nuclear fuel pin subassemblies. As a first step the LES results have been verified a priori and a posteriori in annular channels against DNS data and experimental data to ensure the consistency of the formulation. Then LES has been extensively applied to several eccentric annular channel configurations and confirmed the presence of large-scale coherent structures near the narrow gap. There, the influences of the anisotropic turbulence structure and eddy migration behaviors in the non-uniform flow channels have been investigated in detail. Through the use of statistical tool (POD: Proper Orthogonal Decomposition) it has been validated that even the internal structure of turbulence reflects experimental findings. As a last step the methodology has been extended to rod-bundles, where the same oscillations have been observed.

2. Methodology

In previous research several DNS computations have been performed for the concentric and eccentric channels. The data collected has been used to evaluate different SGS model in order to develop an effective LES methodology in boundary fitted coordinates. Several other models have been tested, among which the dynamic mixed model, the self-similarity model and another variant of the dynamic model [3]. Figure 1 shows an example of a priori test. The dynamic model and its variant performed fairly well from the point of view of a priori and a posteriori tests. They may be considered the ideal choice for the simulation of the flow in annular channels and rod-bundles.

The algorithm used to solve the Navier-Stokes equations is based on the Fractional Step Algorithm on a partially non-staggered grid [4]. The equations have been discretized through a second order consistent scheme [5] and time advancement has been carried out through an Adams-Bashfort scheme. The Poisson equation for the pressure gauge has been solved with either:
1. An FFT solver (since periodic boundary conditions have been employed in the streamwise direction) for eccentric channels; or

The multiblock solver uses non-overlapping domain decompositions. The domain is divided into a set of non overlapping structured grids. The algorithms employed by the solver are the Conjugate Gradient Squared CGS and Bi-Conjugate Gradient [7]. A two-level preconditioning (block-level and upper level) has been adopted [8]. Alternatively, for large scale calculations a geometric multi-grid preconditioning has also been implemented.
3. Results for eccentric channels

An extensive LES computational campaign has been performed for the eccentric channel at various Reynolds numbers and the eccentricity to investigate the characteristics of the flow in eccentric channels. Some of the cases run are reported in Table 1 for different values of the geometric parameters $D_h$ (hydraulic diameter), $\alpha = D_{in}/D_{out}$ and $e = d(D_{out} - D_{in})$ where $D_{in}$ and $D_{out}$ are the inner and outer diameters and $d$ is the distance between the axis of the two cylinders. The computation of some of the cases took a considerable amount of time since all scales of turbulence above the inertial range need to be simulated, the DNS case used to validate the LES model a priori required almost 0.2 billion meshes.

The results of the simulations A, C and D have been validated for available DNS and experimental data [9, 10, 11]. From previous works it appears that the transition to tur-

bulence in geometry such as the eccentric annuli [12] is
accompanied by the formation of a street of counter-rotating
vortices in the region near the narrow gap. These coherent
structures persist at low Reynolds numbers but they progres-
sively become less dominant, at least for an eccentricity
equal to 0.5, as the Reynolds number increases.

Contemporarily, in the narrow gap the local profile of the
streamwise velocity evolves from a purely laminar solution
to a solution characterized by the presence of turbulence
production near walls. The shear stress in the narrow gap
region evolves from an almost laminar condition for a
Reynolds number equal to 3,200 to an increasingly turbulent
solution [12].

At low Reynolds number and eccentricity equal to 0.5 the
relative dominance of the coherent structures is associated
with a strong anisotropy in the narrow gap (turbulence has a
local two-component pattern), while at higher Reynolds
numbers a nearly isotropic condition is recovered far from
the walls. At higher eccentricity (e = 0.95) the coherent
structures are absent in the narrow gap region, accounting
for a strong viscous damping effect in the case of almost
touching channels.

When Reynolds averaging is performing over the flow
field, secondary vortices are observed in the cross section. In
Fig. 3, an example is shown for case A. The shape of the
secondary flows depends on the value of the eccentricity e
and the parameter $\alpha$ [12].

4. Proper Orthogonal Decomposition

A POD (Proper Orthogonal Decomposition) study [13] of
the fields obtained in this study has been performed to obtain
additional insight in the physics of flow in eccentric chan-
nels. The power of the POD lies in the fact that the decom-
position $\sigma_i(\tilde{x})$ of the flow field in the POD eigen-functions:

$$\tilde{u}(\tilde{x}) = \sum_i a_i \sigma_i(\tilde{x})$$

where $a_i$ are real coefficients, converges optimally fast in L2;
i.e. a truncation of $n$ modes in the POD decomposition is the
optimal possible truncation for the same number of modes.
Each mode is characterized by its energy content, the rank of
the modes based on their energy content will be called
"quantum number" in the following. Detailed description of
the procedure used can be found in Sirovich [14].

The POD has been carried out for case A at $e = 0.5$ with
2000 snapshots. The first 6 modes contain 20% of the total
turbulent kinetic energy. In particular the first four modes
are representative of a traveling wave of the type $\tilde{u} = \tilde{u}_0 \sin
2\pi[(x/\lambda) - (t / T)]$, which can in fact be splitted into two
terms that differ in the axial direction $x$ by a phase shift of
$\pi/2$. Moreover two wavelengths appear to be present. In
fact the use of periodic boundary conditions and a finite
computational length in the streamwise direction imply a
discretized wavenumber spectrum and subsequently the
impossibility for the computation to reproduce exactly the
correct wavenumber spectrum which is inherently continu-
ous (unless the domain is extremely long, in the sense dis-
商ed in [15]).

The most energetic mode of the POD is shown in Fig. 4c
and Fig. 4d. It is characterized by a vortex centered in the
middle of the gap. Similar modes have been found for a two
rectangular channels connected by a narrow gap [15] as
shown in Fig. 4b taken from [15]. Interestingly it is present
both in experimental data [16] as shown in Fig. 4a and in
computations (Fig 4b). It appears that the oscillatory behav-
ior in the narrow gap is dominated by the waves shown in
Fig. 4d which seem a quasi-universal pattern present in
flows containing a narrow gap. Thus, Simulations show a
remarkable success in reproducing the inherent structure of
turbulence giving us additional confidence in the validity of
the present approach.

5. Results for rod bundles

As a preliminary work we have performed the large eddy
simulation of the flow in two-subchannels connected by a
narrow gap (Fig. 5a) with periodic boundary conditions in
the cross section and in the streamwise direction. Figure 5a
displays a snapshot of the transverse velocity field in the
cross section with a detail of the central gap. The vector plot
shows a vortex positioned near the gap driving the cross
flow between the two subchannels, thus mimicking the same
phenomenon described previously for eccentric channels and
other related geometries ([2]). This is even more evident if
the instantaneous cross velocity profile is observed for case
D (Fig. 6). The cross velocity has a sinusoidal behavior that
is consistent with the principal mode of turbulence shown in
Fig. 4.
6. Conclusions

A LES code has been developed on the boundary fitted coordinates, with multi-block domain decomposition and a Dynamic SGS model for the flows in complex geometries, suitable for the simulation of fuel bundles and annular channels. The code has reproduced successfully the turbulent flow features, i.e., presence of secondary flows and the global flow pulsations common to both in annular channels and in rod-bundles. The comparison between Proper Orthogonal Decomposition conducted on experimental data and computational data has also given us confidence that the present methodology is able to reproduce the inner structure of turbulence in geometry containing a narrow gap.

本研究の目的は、流路チャンネルが複雑で実験計測上取得困難な詳細な流速分布、乱流特性などを高い信頼性の裏づけをもった直接乱流シミュレーション (DNS) および大渦シミュレーション (LES) によって提供し、現象の解明を実施するともに現象の機構論的なモデル化を行って高速増殖炉などの集合体設計および原子炉安全性評価に必要な乱流熱流動データベースの構築をすることにとともに工学的応用に有効に活用することである。

複雑形状流路の典型である高度炉または低減速型軽水炉炉心における細密格子配列型燃料集合体サブチャンネル内の乱流構造のRe数依存性や配列格子のビッチ対燃料直径比に対する依存性は現象論的に極めて複雑である。その現象解明を行うには計算科学的手法が唯一の手段と考えられる。細密格子燃料集合体内サブチャンネル内の乱流は、燃料要素間隔が狭いため壁の影響を強く受け、非等力性が強い。一般的に燃料集合体内の乱流は、P/Dの減少およびRe数が低くなると燃料間隔部近傍でその非均質性が増すとともに、局所的な乱流－層流遷移領域を含み、流れそのものが不安定となることが予測される。

本稿は、境界適応型座標系上のLESを用い、偏心二重円環流路内流路における十分に発達した乱流と燃料集合体内流路における乱流挙動の類似性に着目して実施した解析結果に基づき、主流方向流れの時間平均流速分布、せん断応力、各振わり成分のRMSなどについて、これまでに得られている直接乱流シミュレーション結果および実験データと比較して十分な精度で一致していることの確認を行うとともに、乱流形状の非一様性から生じる二次流れによって輸送される乱流渦の動的な挙動と主流方向における大規模な流れとの相互作用、これらの乱流形状とRe数依存性の解明に関する報告である。とくに低Re数条件下では、狭隘ギャップ部における層流と乱流の遷移現象、軸方向スパンに見た大断面的な乱流場におけるコヒーレントな振動モードを同定することができた。また、高Re数領域に至っては、等力的な乱流場へ移行し、こうした局所的な乱流－層流遷移現象および大断面の振動現象が消滅することを明らかにした。また、脈動三次元時間依存の乱流計算結果の図形処理のみでは理解しきれない可能性がある物理情報の抽出に、POD (Proper Orthogonal Decomposition) を適用して複雑な乱流構造の動的な挙動を客観的に示すことにより、流量特性間の遷移、局所および大局の流れの振動モード発現のメカニズムを説明した。
